

**P E2** (pg 1 of 2) **Writing & Naming Ionic Formulas**  
(How do you know when you need the Roman Numeral?)

Name \_\_\_\_\_

*Write the formula or the name (as appropriate) for the following compounds.*

- |                            |                             |
|----------------------------|-----------------------------|
| 1. iron(II) fluoride       | 11. nickel(II) bromide      |
| 2. lead(IV) chloride       | 12. tin(IV) iodide          |
| 3. copper(I) oxide         | 13. sodium oxide            |
| 4. chromium (VI) sulfide   | 14. manganese (VII) sulfide |
| 5. antimony(V) nitride     | 15. vanadium(V) nitride     |
| 6. $\text{MnO}_2$          | 16. $\text{PbO}_2$          |
| 7. $\text{CuO}$            | 17. $\text{FeS}$            |
| 8. $\text{InF}_3$          | 18. $\text{AlCl}_3$         |
| 9. $\text{Cr}_2\text{S}_3$ | 19. $\text{Mn}_2\text{S}_3$ |
| 10. $\text{CuCl}$          | 20. $\text{HgCl}$           |

**Answers - Writing & Naming Ionic Compounds**

1.  $\text{Fe}^{2+}$   $\text{F}^-$  criss-cross to get  $\text{FeF}_2$
2.  $\text{Pb}^{4+}$   $\text{Cl}^-$  criss-cross to get  $\text{PbCl}_4$
3.  $\text{Cu}^+$   $\text{O}^{2-}$  criss-cross to get  $\text{Cu}_2\text{O}$
4.  $\text{Cr}^{6+}$   $\text{S}^{2-}$  criss-cross to get  $\text{CrS}_3$
5.  $\text{Sb}^{5+}$   $\text{N}^{3-}$  criss-cross to get  $\text{Sb}_3\text{N}_5$
6. Since the oxide carries a  $2^-$  charge, and there is one of each ion, the charge must be the same magnitude, opposite charge, thus Mn must be  $2^+$ , resulting in manganese(IV) oxide
7. Since the oxide carries a  $2^-$  charge, and there is one of each ion, the charge must be the same magnitude, opposite charge, thus Cu must be  $2^+$ , resulting in copper(II) oxide
8. Indium always carries a  $3^+$  charge, thus there is no need for a Roman Numeral, thus simply: indium fluoride
9. Since the sulfide carries a  $2^-$  charge, 3 of them  $\times 2^-$  equals  $6^-$ , and the chromium ions total charge must be opposite in sign, but equal in magnitude. Thus 2 chromium ions  $\times$  "what charge" =  $6^+$ ? Thus the chromium must be  $3^+$ , resulting in chromium(III) sulfide
10. Since the chloride carries a  $1^-$  charge, and there is one of each ion, the charge must be the same magnitude, opposite charge, thus Cu must be  $1^+$ , resulting in copper(I) chloride
11.  $\text{Ni}^{2+}$   $\text{Br}^-$  criss-cross to get  $\text{NiBr}_2$
12.  $\text{Sn}^{4+}$   $\text{I}^-$  criss-cross to get  $\text{SnI}_4$
13.  $\text{Na}^+$   $\text{O}^{2-}$  criss-cross to get  $\text{Na}_2\text{O}$
14.  $\text{Mn}^{7+}$   $\text{S}^{2-}$  criss-cross to get  $\text{Mn}_2\text{S}_7$
15.  $\text{V}^{5+}$   $\text{N}^{3-}$  criss-cross to get  $\text{V}_3\text{N}_5$
16. Since the oxide ion carries a  $2^-$  charge, 2 of them  $\times 2^-$  equals  $4^-$ , and the lead ions total charge must be opposite in sign, but equal in magnitude. Thus the one lead ion must be  $4^+$  charge, resulting in lead(IV) oxide
17. Since the oxide carries a  $2^-$  charge, and there is one of each ion, the charge must be the same magnitude, opposite charge, thus Fe must be  $2^+$ , resulting in iron(II) sulfide
18. Aluminum always carries a  $3^+$  charge, thus there is no need for a Roman Numeral, resulting in aluminum chloride
19. Since the sulfide carries a  $2^-$  charge, 3 of them  $\times 2^-$  equals  $6^-$ , and the manganese ions total charge must be opposite in sign, but equal in magnitude. Thus 2 manganese ions  $\times$  "what charge" =  $6^+$ ? Thus the manganese must be  $3^+$ , resulting in manganese(III) sulfide
20. Since the chloride carries a  $1^-$  charge, and there is one of each ion, the charge must be the same magnitude, opposite charge, thus Hg must be  $1^+$ , resulting in mercury(I) chloride
